Question <b>2</b>	
Not yet answered	
Marked out of 10.00	

Suppose that you're going to run linear regression with some input features and 1 output feature. Your hypothesis is

$$h_{ heta}(X) = heta_0 + heta_1 X_1 + heta_2 X_2 + heta_3 X_1^2 + heta_4 X_1^3 + heta_5 X_2^2 + heta_6 X_2^3 + heta_7 (X_1 \cdot X_2) + heta_8 (X_1^2 \cdot X_2)$$

Firstly it it necessary to normalize your dataset: Z = (x-mu)/std

Initial theta parameters is equal to zero. Learning rate is 0.1. Now, let's complete the following table:

#Iterations	Cost Function (Round please	Optimal Theta parameter
	up to integer value)	Indicate here maximum theta value(Round
		please up to integer value)
n=10		
n=100		
n=1000		

1	2	3	4	5	6	7	8	9	0
---	---	---	---	---	---	---	---	---	---

Question 3

Not yet answered

Marked out of 10.00

Suppose that you have the following dataset, with 3 input features, and 1 output feature. You're going to apply Logistic Regression algorithm with regularization.

Firstly it is necessary to apply normalization with the following formula: Z = (X-mu)/std.

Initial theta parameters = 0.

#Iterations, lambda, learning	Cost function (rounded up to 2	Optimal theta parameter
rate		Indicate here maximum theta value (rounded up to 2 digis after floating point)
N=100, alpha = 0.1, lambda = 0.1		
N=1000, alpha = 0.2, lambda = 1		
N=10000, alpha = 0.3, lambda = 10		

After 10.000 iterations, alpha = 0.3, lambda = 10 and by setting threshold = 0.5, what is the number of ones in the first 10 rows of prediction:

_											
	1	2	3	4	5	6	7	8	9	0	,

Question <b>4</b>	
lot yet answered	
Marked out of 10.00	
Suppose that you're going to run neural network algorithm with the following parameters:	
1. Data Preparation: Normalized input vectors for binary classification.	
2. Network Architecture: 3 hidden layers with Tanh, output layer with Sigmoid.	
3. Forward Propagation: Computes activations through layers.	
4. Loss Calculation: Uses Mean Absolute Error (MAE) as the loss function.	
<ol> <li>Backpropagation: Computes gradients using chain rule and Tanh derivative.</li> <li>Weight and Bias Updates: Uses gradient descent with learning rate 0.1.</li> </ol>	
7. Iterative Training: Runs for 10,000 epochs, prints loss every 1000 epochs.	
8. Final Prediction: Generates probabilities for each input.	
a4 = [	
W4.max() = (round up to 2 digits after floating point)	
W3.min() = (round up to 2 digits after floating point)	
Loss after 10000 epochs:	
General Conculsion after 10000 epochs:	
deficial concasion after 10000 epochs.

NN predicts image of dog NN predicts image of cat NN can't define of	correct image class

Question <b>5</b>	
Not yet answered	
Marked out of 9.00	

For a multi-class classification problem, we don't calculate an overall F-1 score. Instead, we calculate the F-1 score per class in a one-vs-rest manner. In this approach, we rate each class's success separately, as if there are distinct classifiers for each class.

Suppose that you are running logistic regression with some threshold and now you have the following in Table 1.

Table 1

		Actual Class					
		а	b	С			
Predicted Class	а	30	20	10			
	b	50	60	10			
	С	20	20	80			

- a) Firstly, calculate the accuracy of algorithm
- b) Find precision and recall for each classes a, b and c. Hint:
- c) Calculate F1-score for each class a, b and c.

For part b and c please transfer your answers into table below:

Class	Precision	Recall	F1-score		
a					
b					
С					

Please round up to 3 digits after floating point

1	2	3	4	5	6	7	8	9	0	,
